

# **Exceptional Control Flow: Exceptions and Processes**

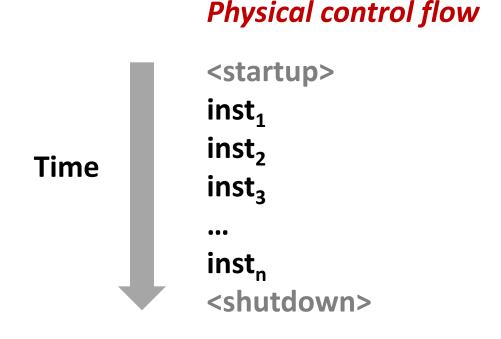

Exceptions

These slides adapted from materials provided by the textbook authors.

- Exceptional Control Flow
- Exceptions
- Processes
- Process Control

### **Control Flow**

- Processors do only one thing:
  - From startup to shutdown, a CPU simply reads and executes (interprets) a sequence of instructions, one at a time
  - This sequence is the CPU's control flow (or flow of control)

# **Altering the Control Flow**

- Up to now: two mechanisms for changing control flow:
  - Jumps and branches
  - Call and return

React to changes in *program state* 

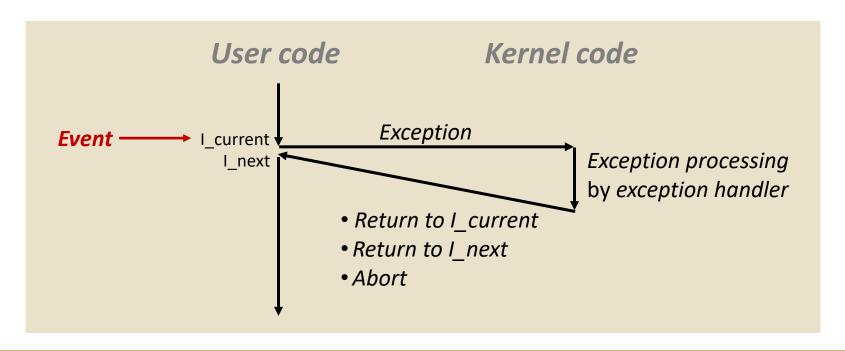

- Insufficient for a useful system:
  Difficult to react to changes in system state
  - Data arrives from a disk or a network adapter
  - Instruction divides by zero
  - User hits Ctrl-C at the keyboard
  - System timer expires
- System needs mechanisms for "exceptional control flow"

- Exists at all levels of a computer system
- Low level mechanisms
  - 1. Exceptions
    - Change in control flow in response to a system event (i.e., change in system state)
    - Implemented using combination of hardware and OS software
- Higher level mechanisms
  - 2. Process context switch
    - Implemented by OS software and hardware timer
  - 3. Signals
    - Implemented by OS software
  - 4. Nonlocal jumps: setjmp() and longjmp()
    - Implemented by C runtime library

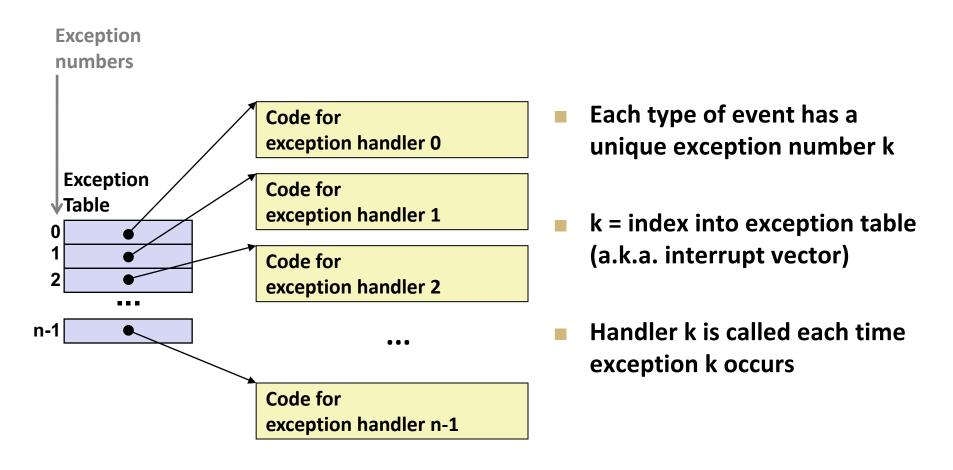

- Exceptional Control Flow
- Exceptions
- Processes
- Process Control

### **Exceptions**

- An exception is a transfer of control to the OS kernel in response to some event (i.e., change in processor state)
  - Kernel is the memory-resident part of the OS
  - Examples of events: Divide by 0, arithmetic overflow, page fault, I/O request completes, typing Ctrl-C

### **Exception Tables**

# **Asynchronous Exceptions (Interrupts)**

### Caused by events external to the processor

- Indicated by setting the processor's interrupt pin
- Handler returns to "next" instruction

### Examples:

- Timer interrupt
  - Every few ms, an external timer chip triggers an interrupt
  - Used by the kernel to take back control from user programs
- I/O interrupt from external device
  - Hitting Ctrl-C at the keyboard
  - Arrival of a packet from a network
  - Arrival of data from a disk

### **Synchronous Exceptions**

Caused by events that occur as a result of executing an instruction:

### Traps

- Intentional
- Examples: system calls, breakpoint traps, special instructions
- Returns control to "next" instruction

#### Faults

- Unintentional but possibly recoverable
- Examples: page faults (recoverable), protection faults (unrecoverable), floating point exceptions
- Either re-executes faulting ("current") instruction or aborts

#### Aborts

- Unintentional and unrecoverable
- Examples: illegal instruction, parity error, machine check
- Aborts current program

# **System Calls**

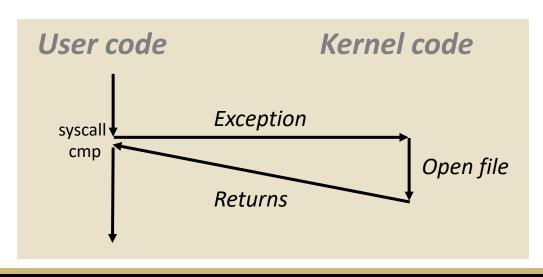

- Each x86-64 system call has a unique ID number
- Examples:

Number	Name	Description
0	read	Read file
1	write	Write file
2	open	Open file
3	close	Close file
4	stat	Get info about file
57	fork	Create process
59	execve	Execute a program
60	_exit	Terminate process
62	kill	Send signal to process

### System Call Example: Opening File

- User calls: open (filename, options)
- Calls \_\_open function, which invokes system call instruction syscall

```
00000000000e5d70 <__open>:
e5d79:
         b8 02 00 00 00
                                  $0x2,%eax # open is syscall #2
                             mov
e5d7e:
         0f 05
                                             # Return value in %rax
                             syscall
e5d80:
      48 3d 01 f0 ff ff
                                  $0xffffffffffff001,%rax
                             CMD
e5dfa:
         c3
                             retq
```

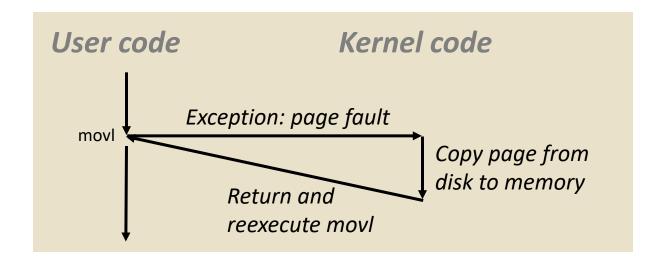

- %rax contains syscall number
- Other arguments in %rdi, %rsi, %rdx, %r10, %r8, %r9
- Return value in %rax
- Negative value is an error corresponding to negative errno

# Fault Example: Page Fault

- User writes to memory location
- That portion (page) of user's memory is currently on disk

```
int a[1000];
main ()
{
    a[500] = 13;
}
```

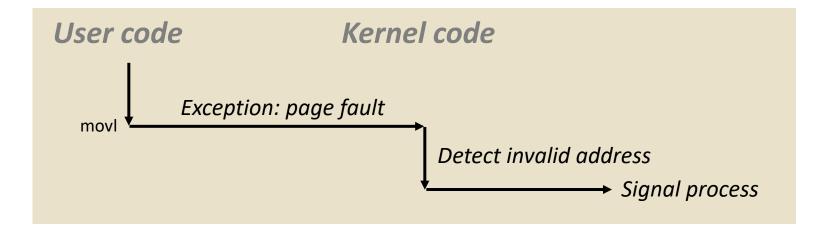

```
80483b7: c7 05 10 9d 04 08 0d movl $0xd,0x8049d10
```

### Fault Example: Invalid Memory Reference

```
int a[1000];
main ()
{
    a[5000] = 13;
}
```

```
80483b7: c7 05 60 e3 04 08 0d movl $0xd,0x804e360
```

- Sends SIGSEGV signal to user process
- User process exits with "segmentation fault"

- Exceptional Control Flow
- Exceptions
- Processes
- Process Control
