12.1 Set abstract data type

Set abstract data type

A **set** is a collection of distinct elements. A set **add** operation adds an element to the set, provided an equal element doesn't already exist in the set. A set is an unordered collection. Ex: The set with lintegers 3, 7, and 9 is equivalent to the set with integers 9, 3 and 7.

Element keys and removal

Set elements may be primitive data values, such as numbers or strings, or objects with numerous data members. When storing objects, set implementations commonly distinguish elements based on an element's **key value**: A primitive data value that serves as a unique identifier for the element. Ex: An object for a student at a university may store information such as name, phone number, and ID number. No two students will have the same ID number, so the ID number can be used as the student object's key.

Sets are commonly implemented to use keys for all element types. When storing objects, the set retrieves an object's key via an external function or predetermined knowledge of which object property is the key value. When storing primitive data values, each primitive data value's key is itself.

Given a key, a set **remove** operation removes the element with the specified key from the set.

12.2 Set operations

Union, intersection, and difference

The **union** of sets X and Y, denoted as X \cup Y, is a set that contains every element from X, every element from Y, and no additional elements. Ex: { 54, 19, 75 } \cup { 75, 12 } = { 12, 19, 54, 75 }.

The *intersection* of sets X and Y, denoted as X \cap Y, is a set that contains every element that is in both X and Y, and no additional elements. Ex: $\{54, 19, 75\} \cap \{75, 12\} = \{75\}$.

The **difference** of sets X and Y, denoted as $X \setminus Y$, is a set that contains every element that is in X but not in Y, and no additional elements. Ex: $\{54, 19, 75\} \setminus \{75, 12\} = \{54, 19\}$.

The union and intersection operations are commutative, so $X \cup Y = Y \cup X$ and $X \cap Y = Y \cap X$. The difference operation is not commutative.

PARTICIPATION ACTIVITY

12.2.1: Set union, intersection, and difference.

Animation content:

undefined

Animation captions:

- 1. The union operation begins by adding all elements from set1.
- 2. Each element from set2 is added. Adding elements 82 and 93 has no effect, since 82 and 93 already exist in the result set.
- 3. The intersection operation iterates through each element in set1. Each element that is also in set2 is added to the result.
- 4. The difference of set1 and set2, denoted set1 \ set2, iterates through all elements in set1. Only elements 61 and 76 are added to the result, since these elements are not in set2.
- 5. Set difference is not commutative. SetDifference(set2, set1) produces a result containing only 23 and 46, since those elements are in set2 but not in set1.

$\bigcirc X \setminus X = X \cap X$	

Filter and map

A *filter* operation on set X produces a subset containing only elements from X that satisfy a particular condition. The condition for filtering is commonly represented by a *filter predicate*: A function that takes an element as an argument and returns a Boolean value indicating whether or not that element will be in the filtered subset.

A **map** operation on set X produces a new set by applying some function F to each element. Ex: If $X = \{18, 44, 38, 6\}$ and F is a function that divides a value by 2, then SetMap(X, F) = $\{9, 22, 19, 3\}$.

PARTICIPATION ACTIVITY

12.2.3: SetFilter and SetMap algorithms.

Animation content:

undefined

Animation captions:

- 1. SetFilter is called with the EvenPredicate function passed as the second argument.
- 2. SetFilter calls EvenPredicate for each element. EvenPredicate returns true for each even element, and false for each odd element.
- 3. Every element for which the predicate returned true is added to the result, producing the set of even numbers from set1.
- 4. SetFilter(set1, Above90Predicate) produces the set with all elements from set1 that are greater than 90.
- 5. SetMap is called with the OnesDigit function passed as the first argument. Like SetFilter, SetMap calls the function for each element.
- 6. The returned value from each OnesDigit call is added to the result set, producing the set of distinct ones digit values.
- 7. SetMap(set1, StringifyElement) produces a set of strings from a set of numbers.

12.3 Static and dynamic set operations

A *dynamic set* is a set that can change after being constructed. A *static set* is a set that doesn't change after being constructed. A collection of elements is commonly provided during construction of a static set, each of which is added to the set. Ex: A static set constructed from the list of integers (19, 67, 77, 67, 59, 19) would be { 19, 67, 77, 59 }.

Static sets support most set operations by returning a new set representing the operation's result. The table below summarizes the common operations for static and dynamic sets.

Table 12.3.1: Static and dynamic set operations.
